

10nd Week

Average-Case Complexity and Real Computability

Synopsis.

- Average-Case Complexity
- Complexity of Distributions
- Real Computability
- Nearly-BPP

June 11, 2018. 23:59

Course Schedule: 16 Weeks

Subject to Change

- **Week 1:** Basic Computation Models
- **Week 2:** NP-Completeness, Probabilistic and Counting Complexity Classes
- **Week 3:** Space Complexity and the Linear Space Hypothesis
- **Week 4:** Relativizations and Hierarchies
- **Week 5:** Structural Properties by Finite Automata
- **Week 6:** Type-2 Computability, Multi-Valued Functions, and State Complexity
- **Week 7:** Cryptographic Concepts for Finite Automata
- **Week 8:** Constraint Satisfaction Problems
- **Week 9:** Combinatorial Optimization Problems
- **Week 10:** Average-Case Complexity
- **Week 11:** Basics of Quantum Information
- **Week 12:** BQP, NQP, Quantum NP, and Quantum Finite Automata
- **Week 13:** Quantum State Complexity and Advice
- **Week 14:** Quantum Cryptographic Systems
- **Week 15:** Quantum Interactive Proofs
- **Week 16:** Final Evaluation Day (no lecture)

YouTube Videos

- This lecture series is based on numerous papers of **T. Yamakami**. He gave **conference talks (in English)** and **invited talks (in English)**, some of which were video-recorded and uploaded to YouTube.
- Use the following keywords to find a playlist of those videos.
- **YouTube search keywords:**
Tomoyuki Yamakami conference invited talk playlist

Conference talk video

I. Polynomial on Average

1. Worst-Case and Average-Case Analysis
 2. Distributions and Density Functions
 3. Standard Distributions
 4. Polynomial-Time Computable Distributions
 5. Distributional Decision problems
 6. P on μ -Average
 7. Polynomial on Average
 8. Average P , Average NP , and Average BPP
- 

Worst-Case and Average-Case Analysis

- There are a few reasons that we usually concentrate on finding only the **worst-case** running time, that is, **the longest running time** for any input of size n .
 - The worst-case running time of an algorithm is an upper bound on the running time for any input.
 - For some algorithms, the worst case occurs fairly often.
- In some particular cases, we shall be interested in the **average-case** (or expected) running time of an algorithm.
- For average-case analysis, we need to discuss distributional problems whose inputs occur according to certain probability distributions.

Distributions and Density Functions I

- Let $\Sigma = \{ 0, 1 \}$.
- We use the **lexicographic order** over $\{0,1\}^*$, defined as
$$\lambda < 0 < 1 < 00 < 01 < 10 < 11 < 000 < 001 < \dots$$
- Here, “**polynomials**” are to have **integer coefficients**.
- A **semi-distribution** μ is an increasing function from Σ^* to $\mathbb{R}^{\geq 0}$ (i.e., set of nonnegative real numbers).

- A **distribution** μ is a semi-distribution that satisfies

$$\lim_{x \rightarrow \infty} \mu(x) = 1$$

where “ $x \rightarrow \infty$ ” means that x is becoming “larger” according to the lexicographic order, described above.

Distributions and Density Functions II

- In other words, a **distribution** μ is an increasing function from Σ^* to $[0,1]$ such that $\lim_{x \rightarrow \infty} \mu(x) = 1$

- A **(probability) density function** μ^* is defined by

$$\mu^*(x) = \begin{cases} \mu(\lambda) & \text{if } x = \lambda, \\ \mu(x) - \mu(x^-) & \text{otherwise} \end{cases}$$

- A probability density function is also called a **probability distribution**.
- **(Claim)** $\mu(x) = \sum_{z \leq x} \mu^*(z)$ holds, where \leq is the lexicographic ordering.

Notational Remarks

- We use an appropriate encoding $\langle x, 0^i \rangle$ of pair x and 0^i .
- Our algorithm (or a machine) M takes inputs of the form $\langle x, 0^i \rangle$ and eventually enters either accepting or rejecting states.
- Although we actually use encoded strings $\langle x, 0^i \rangle$, for the sake of convenience, we write $M(x, 0^i)$ instead of $M(\langle x, 0^i \rangle)$ for an algorithm (or a machine) M .

Standard Distribution on $\{0,1\}^*$ I

- Let $llog(n) = \lfloor \log_2(n+1) \rfloor$.
- $llog(0)=0$, $llog(1)=1$, $llog(2)=1$, $llog(3)=2$,
- Here is the standard density function on $\{0,1\}^*$.

$$\nu_{\text{stand}}^*(x) = 2^{-|x|} \cdot 2^{-2llog(|x|)-1}$$

- This means that we pick a natural number at random and pick a string of length n at random.

$$\frac{1}{8(|x|+1)^2 2^{|x|}} \leq \nu_{\text{stand}}^*(x) \leq \frac{1}{2(|x|+1)^2 2^{|x|}}$$

Standard Distribution on $\{0,1\}^*$ II

- Its distribution is shown as

$$v_{\text{stand}}(x) = 1 - \frac{3}{2^{\lceil \log(|x|-1)+1}} + \frac{|x|+1}{2^{2\lceil \log(|x|-1)+1}} + \frac{k+1}{2^{2\lceil \log(|x|)+|x|+1}}$$

when x is the k -th string.

- Recall the lexicographic order:

$\lambda < 0 < 1 < 00 < 01 < 10 < 11 < 000 < 001 < \dots$

0 1 2 3 4 5 6 7 8

Standard Distribution on $\{0\}^*$

- A string over a single alphabet is called **tally**.
- Here is the standard density function on $\{0\}^*$.

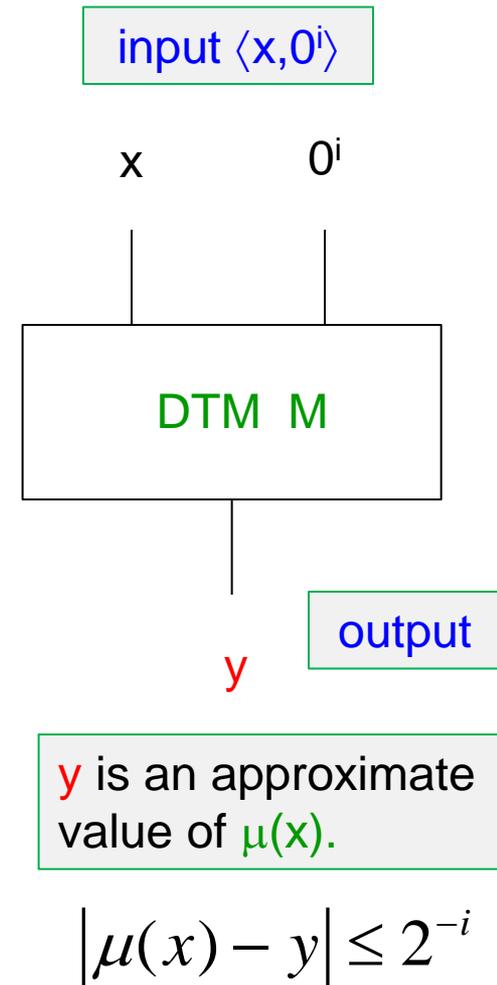

$$\nu_{tally}^*(x) = \begin{cases} 1/2 & \text{if } x = \lambda, \\ 2^{-2\lceil \log(n) \rceil - 1} & \text{if } \exists n > 0 [x = 0^n], \\ 0 & \text{otherwise.} \end{cases}$$

- This means that we pick a natural number at random.
- Its distribution is shown as

$$\nu_{tally}^*(0^n) = \begin{cases} 1/2 & \text{if } n = 0; \\ 2^{-2\lceil \log(n) \rceil - 1} & \text{otherwise.} \end{cases}$$

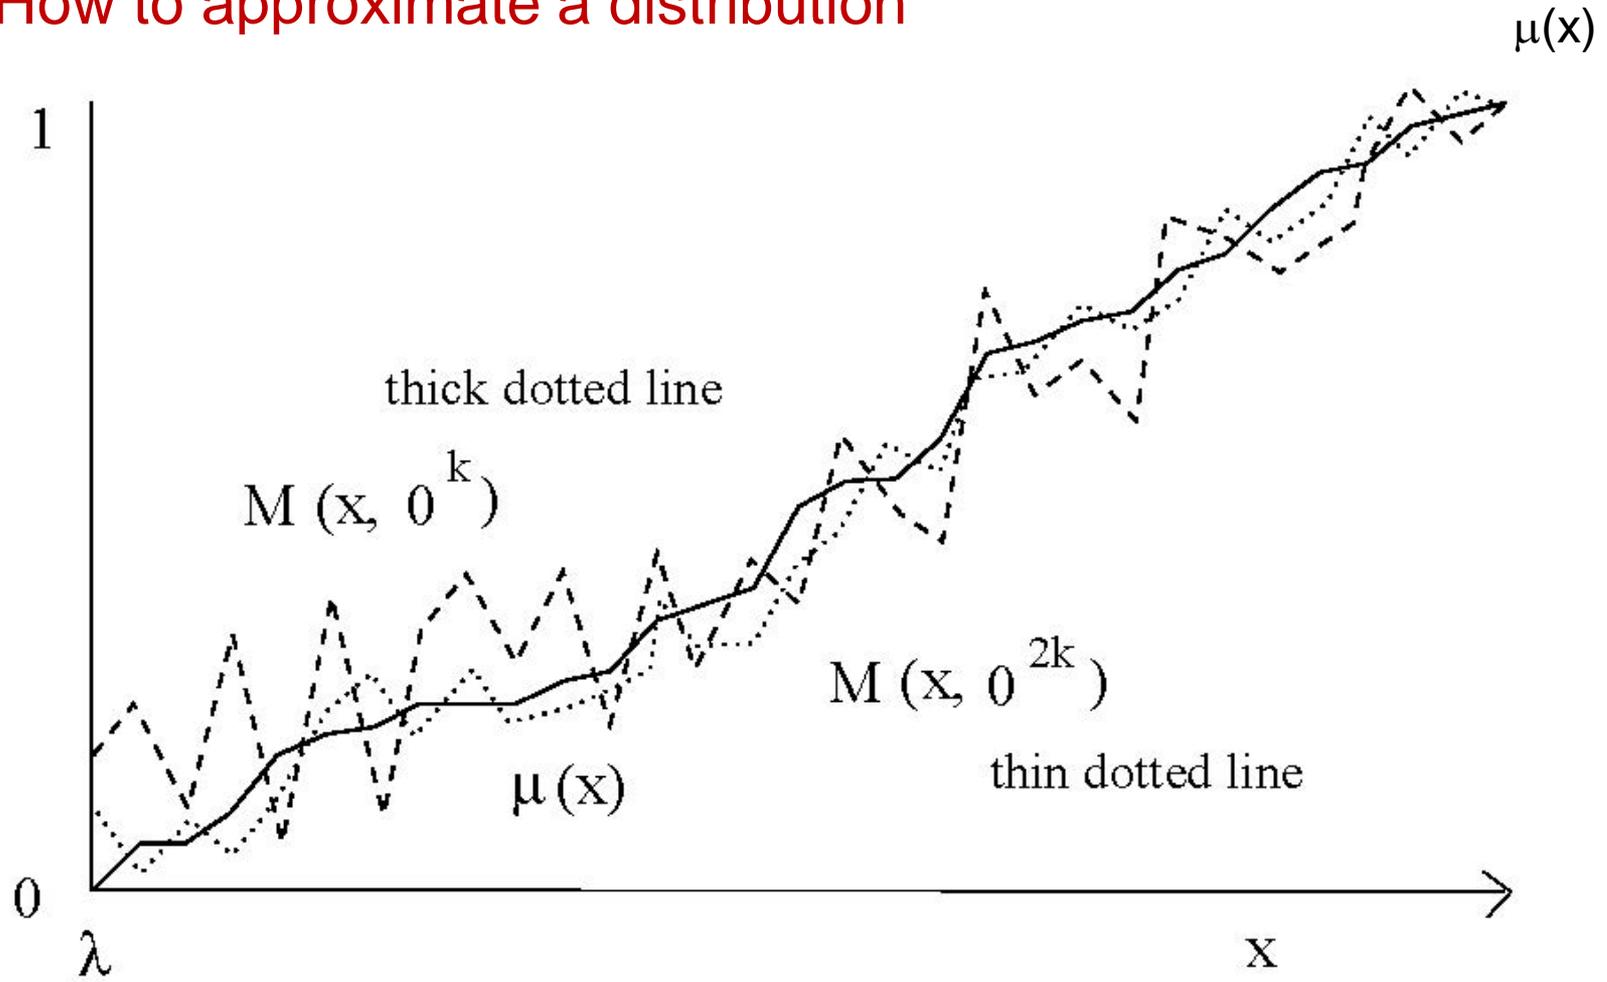

Polynomial-Time Computable Distributions

- Let $\mu: \Sigma^* \rightarrow [0,1]$ be any distribution.
- μ is **polynomial-time computable** \Leftrightarrow there is a polynomial-time deterministic Turing machine (DTM) with an output tape such that
$$|\mu(x) - M(x, 0^i)| \leq 2^{-i}$$
for any $x \in \Sigma^*$ and $i \in \mathbb{N}$.
- Let **P-comp** be the collection of all polynomial-time computable distributions.

Approximation of Distributions

- How to approximate a distribution

As we increase k , $M(x, 0^k)$ is approaching to $\mu(x)$

Distributions Versus Density Functions

- We have defined the **polynomial-time computable distributions** and we will use them as a basis of our polynomial-time computability in average-case complexity theory.
- It could be possible to introduce **polynomial-time computable density functions** and develop average-case complexity theory. However, we did not use density functions in place of distributions.
- This is because:
 - If $P \neq NP$ (as many researchers believe), there exists a density function that is computable in polynomial time but its associated distribution is **not** polynomial-time computable.

Distributional Decision Problems

- A **distributional decision problem** is a pair (D, μ) , where D is a language and μ is a distribution.
- Recall **P** (deterministic polynomial-time class) and **NP** (nondeterministic polynomial-time class) from Week 1.
- Let F be a class of distributions.
- **Dist(P, F)** consists of all distributional decision problem (D, μ) such that $D \in P$ and $\mu \in F$.
- **Dist(NP, F)** consists of all distributional problems (D, μ) with $D \in NP$ and $\mu \in F$.

DistNP

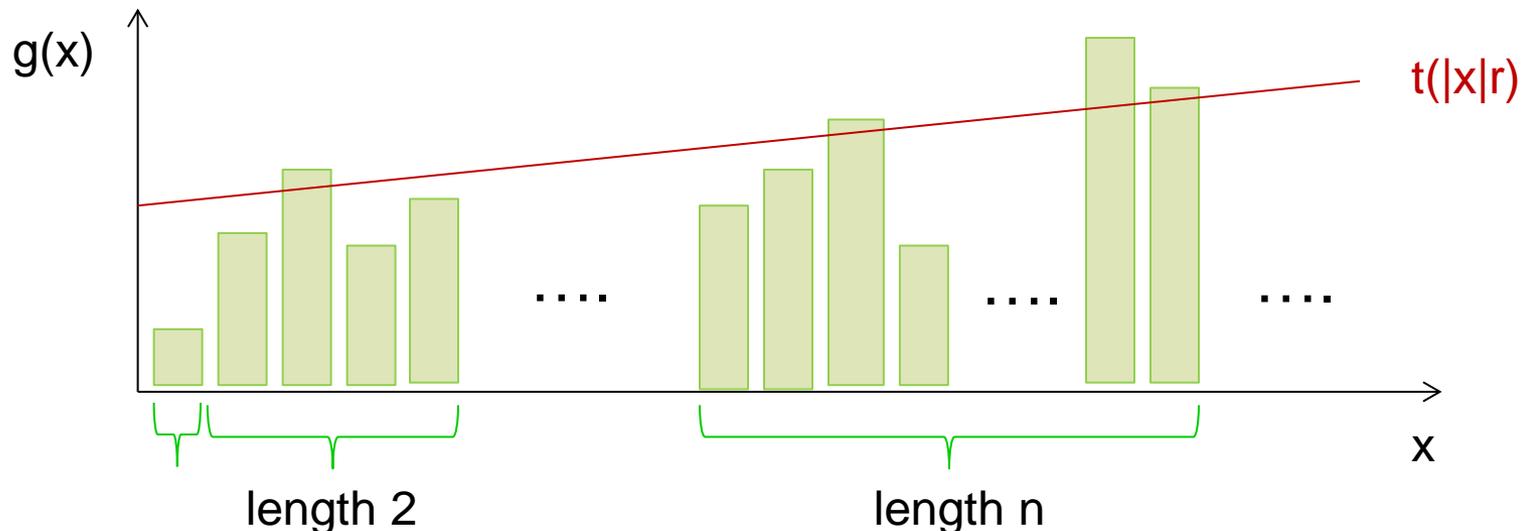

- In the definition of $\text{Dist}(\text{NP}, F)$, if we choose $F =$ all distributions, we write $\text{Dist}(\text{NP}, *)$ for $\{ (D, \mu) \mid D \in \text{NP}, \mu: \text{arbitrary} \}$.
 - Thus, $\text{Dist}(\text{NP}, F) \subseteq \text{Dist}(\text{NP}, *)$ holds for any set F .
- $\text{Dist}(\text{NP}, \text{P-comp})$ is the collection of all distributional decision problem (D, μ) such that $D \in \text{NP}$ and $\mu \in \text{P-comp}$.
 - In this case, we write **DistNP** instead of $\text{Dist}(\text{NP}, \text{P-comp})$.

t on μ -Average

- Let $\mathbb{R}^+ = \{ r \in \mathbb{R} \mid r \geq 0 \}$ and $\mathbb{R}^{+\infty} = \mathbb{R} \cup \{\infty\}$.
- **Schapire** (1990) considered the following. Let $t: \mathbb{R}^+ \rightarrow \mathbb{R}^+$.

- A function $g: \Sigma^* \rightarrow \mathbb{R}^{+\infty}$ is **t on μ -average**
 \Leftrightarrow for any positive real number r ,

$$\mu^* \left(\left\{ x \in \Sigma^* \mid g(x) > t(|x| \cdot r) \right\} \right) < \frac{1}{r}$$

Polynomial on Average

- From the previous definition, we obtain:

- **(Claim)** If g is t on μ -average, then

$$g(x) \leq t(|x|/\mu^*(x))$$

holds for all x with $\mu^*(x) > 0$.

- Let T be a set of functions from \mathbb{R}^+ to \mathbb{R}^+ .

- A function $g: \Sigma^* \rightarrow \mathbb{R}^{+\infty}$ is **T on μ -average**

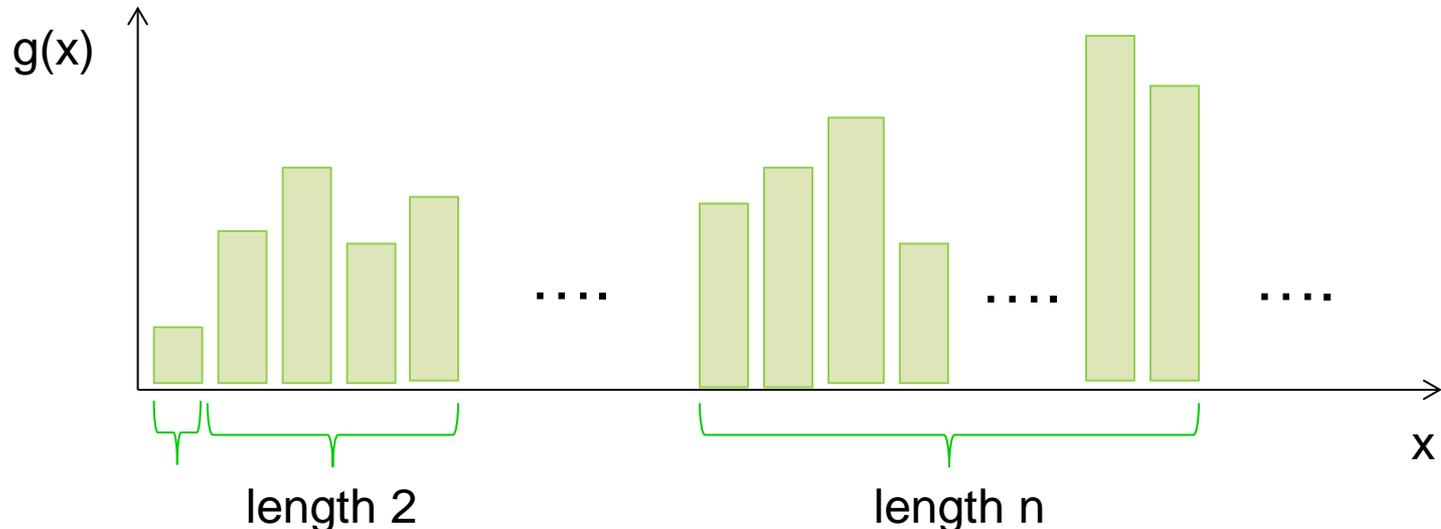

\Leftrightarrow for any $t \in T$, g is t on μ -average.

- In particular, if **$T =$ all positive polynomials**, we obtain the notion of “**polynomial on μ -average.**”

Levin's Definition

- **Levin** (1984) took the following definition.
- A function $g: \Sigma^* \rightarrow \mathbb{R}^{+\infty}$ is **polynomial on μ -average**
 \Leftrightarrow there exists a real number $k \geq 1$ such that

$$\sum_{x:|x|>0} \frac{g(x)^{1/k}}{|x|} \mu^*(x) < \infty$$

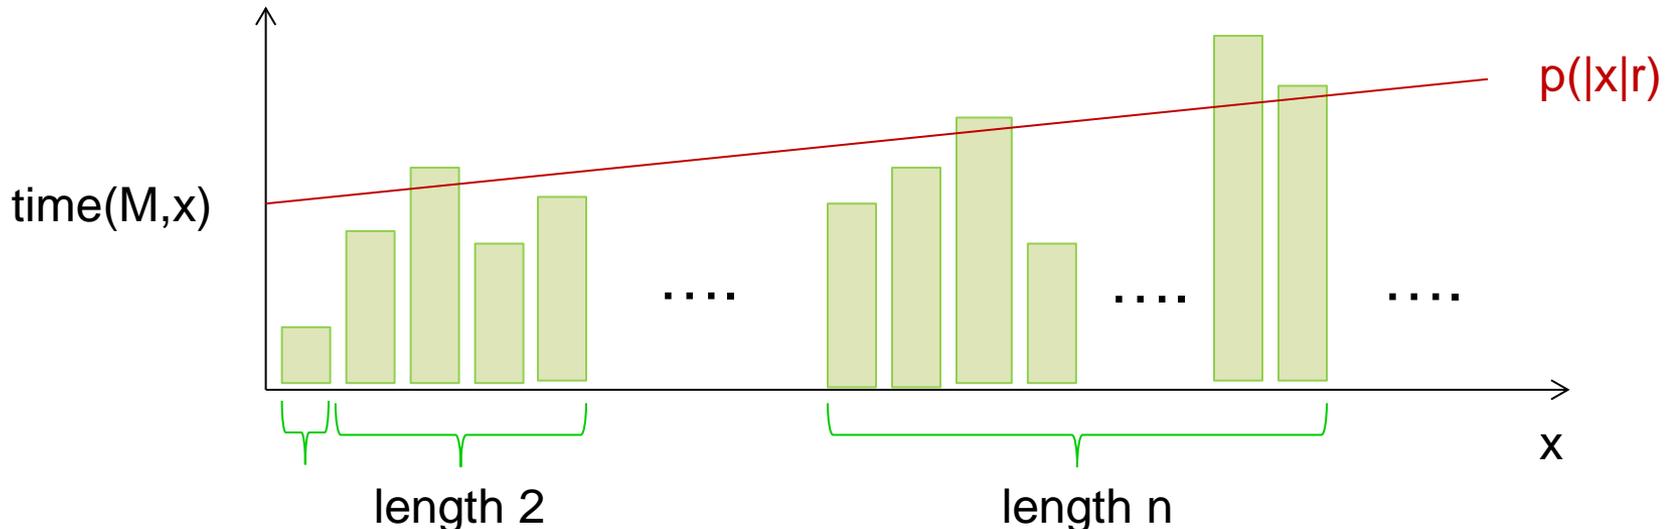

Equivalence Between Two Definitions

- By [Schapire](#) (1990) and [Impagliazzo](#) (1995), we obtain the following equivalence between the previous two definition on “polynomial on μ -average.”
- **(Claim)** The following two definitions are logically equivalent.
 1. g is polynomial on μ -average.
 2. There exists a real number $k \geq 1$ such that

$$\sum_{x:|x|>0} \frac{g(x)^{1/k}}{|x|} \mu^*(x) < \infty$$

Polynomial-Time on Average

- For a deterministic Turing machine (DTM) M and an input x , $\text{time}(M,x)$ means the running time of M on input x .
- Let D be a language over alphabet Σ .
- We say that M **recognizes D in polynomial-time on μ -average** if (i) M recognizes D and (ii) the function $\text{time}(M,\bullet)$ is polynomial on μ -average.

Average P

- Let F be a class of distributions.
- **Average(P,F)** consists of all distributional decision problems (D,μ) such that (i) $\mu \in F$ and (ii) a certain DTM M recognizes D in polynomial-time on μ -average.
- If F is the set of all distributions, we write **Average(P,*).**
- When $F = P\text{-comp}$, we obtain **Average(P,P-comp).** This class is often written as **Average-P.**
- **(Claim)** For any set F of distributions with $v_{\text{tally}} \in F$, **Average(P,F) $\not\subseteq$ Dist(NP,*).** [Wang-Belanger (1995)]

Average NP

- Let F be a class of distributions.
- **Average(NP, F)** consists of all distributional decision problems (D, μ) such that (i) $\mu \in F$ and (ii) certain NTM M recognizes D in polynomial-time on μ -average.
- When $F = P\text{-comp}$, we obtain **Average(NP, P-comp)**. This class is often written as **Average-NP**.
- **(Claim)** $\text{Dist}(\text{NP}) \subseteq \text{Average}(\text{NP}, P\text{-comp})$
- **Theorem:** [Schuler-Yamakami (1992)]
 $\text{Average}(P, *) \neq \text{Average}(\text{NP}, *)$

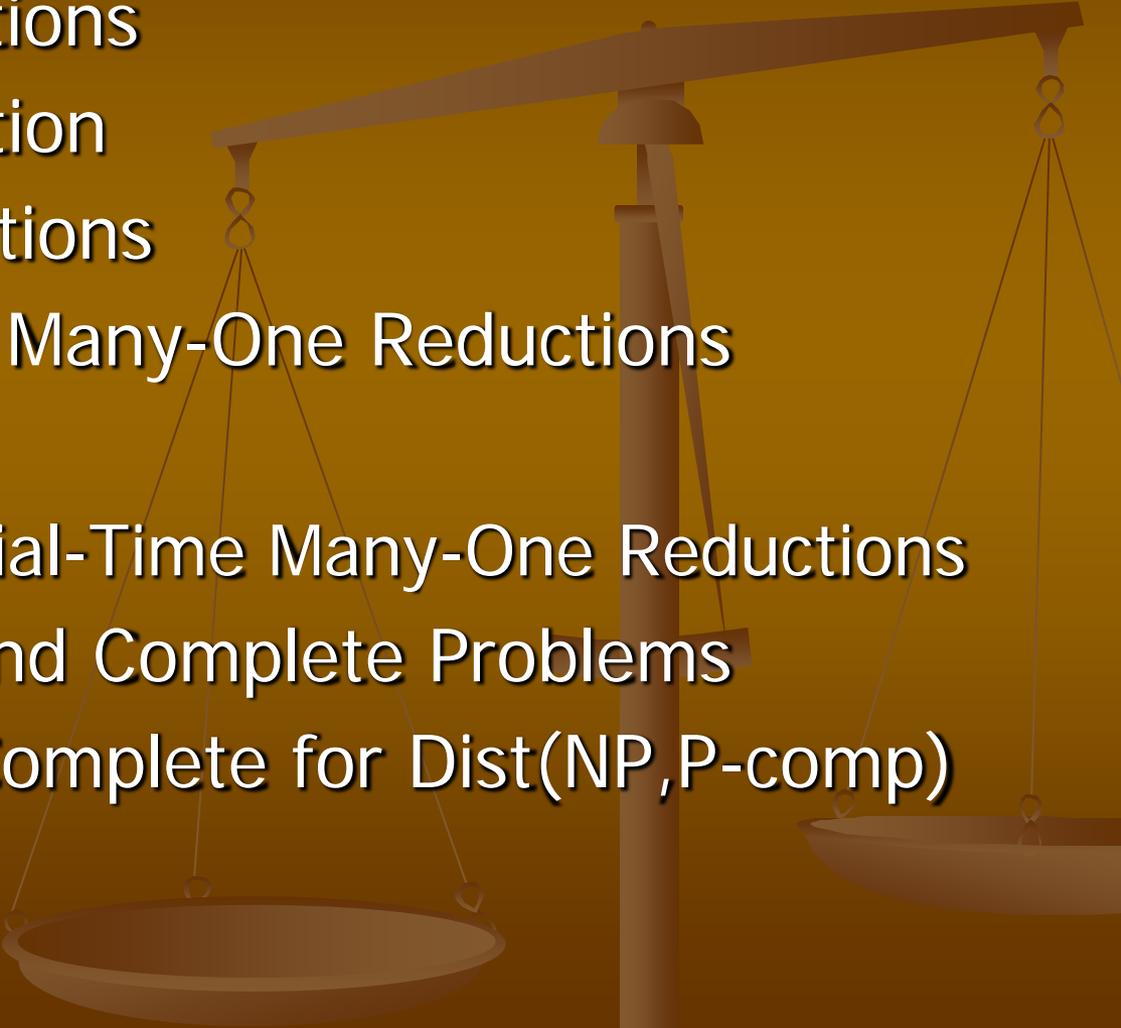

Average BPP

- Let F be a class of distributions.
- **Average(BPP, F)** consists of all distributional decision problems (D, μ) such that (i) $\mu \in F$ and (ii) certain PTM M recognizes D with bounded-error probability in polynomial-time on μ -average.
- When $F = P\text{-comp}$, we obtain **Average(BPP, $P\text{-comp}$)**. This class is often written as **Average-BPP**.
- **Claim:**
 1. If $P \neq BPP$, then $\text{Average}(P, *) \neq \text{Average}(BPP, *)$.
 2. If $P = PP$, then $\text{Average}(P, F) = \text{Average}(BPP, F)$ for any set F of distributions

Open Problems

- At this moment, we do not know whether all distributional problems in DistNP can be solved deterministically in average polynomial time.
- In other words,
- (Open Question) Is $\text{DistNP} \subseteq \text{Average-P}$?
- More generally, we can ask the following question.
- (Open Question)
 - Prove or disprove that $\text{Dist}(\text{NP}, F) \subseteq \text{Average}(\text{P}, F)$ for each choice of natural distribution class F .

II. Complete Distributional Problems

1. Domination Relations
 2. Average Domination
 3. Equivalence Relations
 4. Polynomial-Time Many-One Reductions
 5. Properties of \leq_m^p
 6. Average Polynomial-Time Many-One Reductions
 7. Hard Problems and Complete Problems
 8. $(\text{RBTB}, \mu_{\text{RBTB}})$ is Complete for $\text{Dist}(\text{NP}, \text{P-comp})$
- 

Domination Relations I

- We introduce a notion of “domination.”
- A function $f : \{0,1\}^* \rightarrow \mathbb{R}^{\geq 0}$ is **polynomially bounded** (or **p-bounded**) \Leftrightarrow there exists a polynomial p such that, for all $x \in \{0,1\}^*$, $f(x) \leq p(|x|)$.
- Let μ, ν be distributions and let $t : \{0,1\}^* \rightarrow \mathbb{R}^{\geq 0}$.
- We say that ν **t-dominates** μ if, for all x ,

$$t(x)\nu^*(x) \geq \mu^*(x).$$

- We say that ν **polynomially dominates** (or **p-dominates**) μ ($\mu \leq^p \nu$) if there is a certain polynomially-bounded function t and ν t -dominates μ .

Domination Relations II

- Let μ, ν be distributions.
- **(Claim)** If $\mu_1 \leq^p \mu_2$ and $\mu_2 \leq^p \mu_3$, then $\mu_1 \leq^p \mu_3$.
- **(Claim)** If $\mu_1 \leq^{\text{avp}} \mu_2$ and $\mu_2 \leq^{\text{avp}} \mu_3$, then $\mu_1 \leq^{\text{avp}} \mu_3$.
- **(Claim)** Assume that ν p -dominates μ . If an algorithm A requires polynomial time on ν -average, then A also requires polynomial time on μ -average.

Average Domination

- Let μ, ν be distributions and let $t : \{0,1\}^* \rightarrow \mathbb{R}^{\geq 0}$.
- We say that ν **average t-dominates** μ if there exists a function $f : \{0,1\}^* \rightarrow \mathbb{R}^{\geq 0}$ such that f is t on μ -average and ν f -dominates μ .
- We say that ν **average polynomially dominates** (or **avp-dominates**) μ ($\mu \leq^{\text{avp}} \nu$) if there exists a polynomial t such that ν average t -dominates μ .
- **(Claim)** Assume that ν avp-dominates μ . If an algorithm A requires polynomial time on ν -average, then A also needs polynomial time on μ -average.

Equivalence Relations

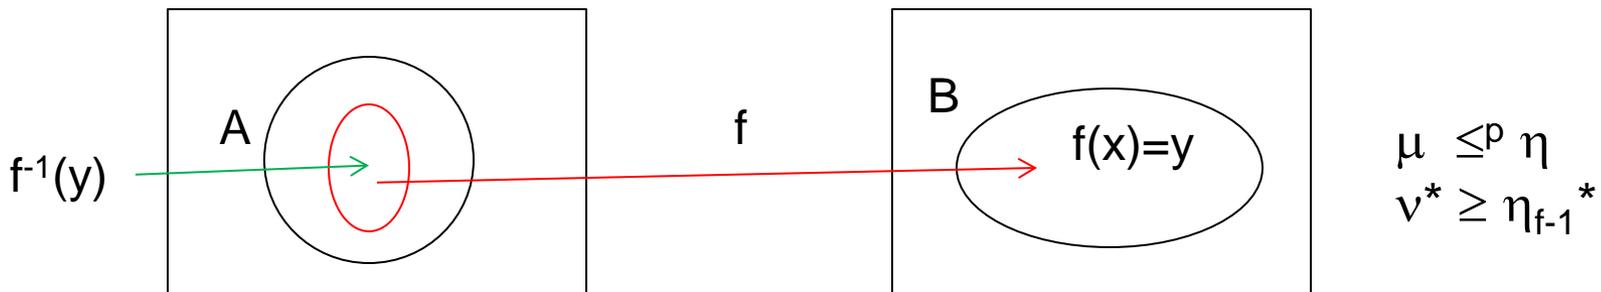

- Let μ, ν be two distributions.
- We say that μ **p-equivalent to ν** ($\nu \approx^p \mu$) if μ p-dominates ν and ν p-dominates μ .
- We say that μ **average p-equivalent to ν** ($\nu \approx^{avp} \mu$) if μ avp-dominates ν and ν avp-dominates μ .

A Useful Condition on Domination

- Let η be a distribution and $f : \Sigma^* \rightarrow \Sigma^*$ be a function.
- Define $\eta_{f^{-1}}$ as $\eta_{f^{-1}}^*(x) = \eta(\{z \mid f(z) = x\})$ for all strings $x \in \Sigma^*$.
- We say that ν^* **majorizes** μ^* (denoted $\nu^* \geq \mu^*$) if $\nu^*(x) \geq \mu^*(x)$ holds for all $x \in \{0,1\}^*$.
- **(Claim)** The following statements are logically equivalent.
 1. There exists a semi-distribution η s.t. $\mu \leq^p \eta$ and $\nu^* \geq \eta_{f^{-1}}^*$.
 2. There exists a p -bounded positive function $p : \{0,1\}^* \rightarrow \mathbb{R}^{\geq 0}$ s.t., for all y ,
$$\nu^*(y) \geq \sum_{x \in f^{-1}(y)} \frac{\mu^*(x)}{p(x)}$$

Polynomial-Time Many-One Reductions

- Let (A, μ) , (B, ν) be any distributional decision problems.
- (A, μ) is **polynomial-time many-one reducible** (or **p-m-reducible**) to (B, ν) iff there exists a function f such that
 - (Efficiency) $f \in \text{FP}$,
 - (Validity) for every x , $x \in A \leftrightarrow f(x) \in B$
 - (Domination) for a certain semi-distribution η , $\mu \leq^p \eta$ and $\nu^* \geq \eta_{f^{-1}}^*$.
- In this case, we write $(A, \mu) \leq_m^p (B, \nu)$.

Properties of \leq_m^p

- The following properties hold.
- **(Reflexive)** $(A, \mu) \leq_m^p (A, \mu)$
- **(Transitive)** If $(A, \mu) \leq_m^p (B, \nu)$ and $(B, \nu) \leq_m^p (C, \eta)$, then $(A, \mu) \leq_m^p (C, \eta)$.
- Hence, \leq_m^p forms a partial order.

Average Polynomial-Time Many-One Reductions

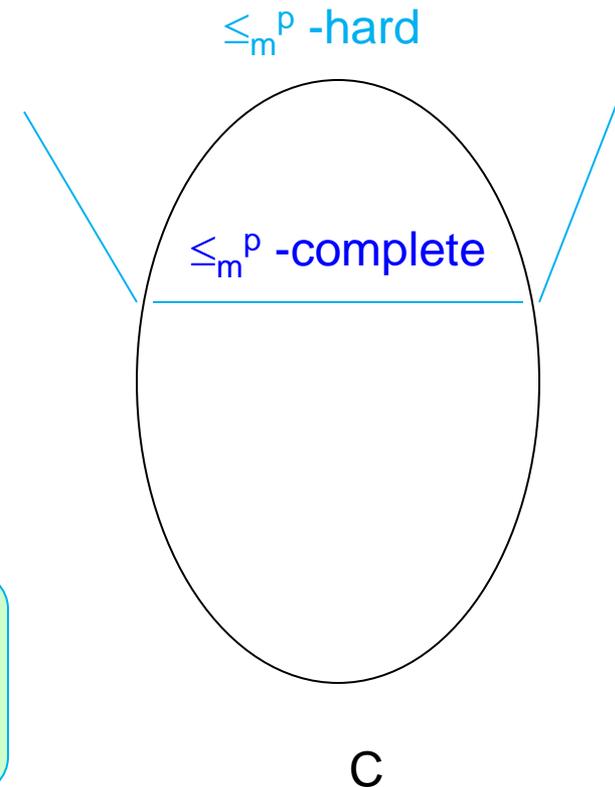

- Let (A, μ) , (B, ν) be any distributional decision problems.
- (A, μ) is **average polynomial-time many-one reducible** (or **avp-m-reducible**) to (B, ν) \Leftrightarrow there exists a function $f : \{0, 1\}^* \rightarrow \{0, 1\}^*$ such that
 - (Efficiency) $(f, \mu) \in \text{Average}(\text{FP}, *)$,
 - (Validity) for every x , $x \in A \leftrightarrow f(x) \in B$
 - (Domination) for a certain η , $\mu \leq^{\text{avp}} \eta$ and $\nu^* \geq \eta_{f''}^*$.
- In this case, we write **$(A, \mu) \leq_m^{\text{avp}} (B, \nu)$** .
- **(Claim)** $(A, \mu) \leq_m^p (B, \nu)$ implies $(A, \mu) \leq_m^{\text{avp}} (B, \nu)$.

Properties

- Let (A, μ) , (B, ν) be any distributional decision problems.
- **(Claim)** For any $C \in \{P, NP, BPP, PSPACE\}$, $\text{Average}(C, *)$ is closed (downward) under \leq_m^{avp} -reductions.
Namely, if $(A, \mu) \leq_m^{\text{avp}} (B, \nu)$ and $(B, \nu) \in \text{Average}(C, *)$, then we obtain $(A, \mu) \in \text{Average}(C, *)$.

Hard Problems and Complete Problems

- Let (A, μ) , (B, ν) be any distributional decision problems.
- Let C be a class of distributional problems.
- (A, μ) is \leq_m^p -hard for C if every distributional problem in C is p - m -reducible to (A, μ) .
- (A, μ) is \leq_m^p -complete for C if (A, μ) is in C and it is \leq_m^p -hard for C .

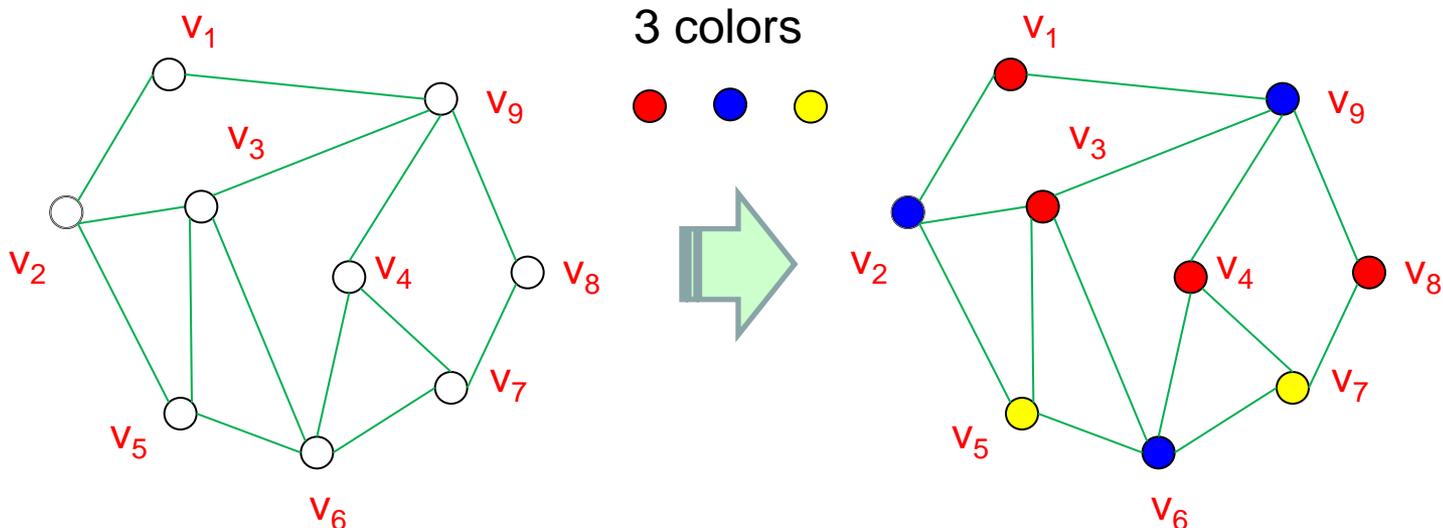

Decision Problems vs. Distributional Problems

- We can ask whether all NP-complete decision problems are also DistNP-complete distributional problems.
- Unfortunately, this statement may not be true, because:
 - 3COL is NP-complete.
 - Wilf (1985) showed that $(3\text{COL}, \mu_{3\text{COL}}) \in \text{Average}(P, *)$.
- In the next slide, we will explain $(3\text{COL}, \mu_{3\text{COL}})$.

Randomized 3-Colorability Problem

- **Randomized 3-Colorability Problem (3COL)**
 - $3COL = \{ \langle G \rangle \mid G \text{ is a graph that is 3-colorable} \}$
 - $\mu_{3COL}^*(\langle G \rangle) = v_{\text{tally}}^*(1^{|V|})2^{-(n \text{ choose } 2)}$
 - (Choose the number of vertices at ransom and then choose edges between pairs of distinct vertices at random.)

Randomized 3-Satisfiability Problem

- Recall that 3SAT is NP-complete.
- **Randomized 3-Satisfiability Problem (3SAT)**
 - $3SAT = \{ \langle (p_1, q_1, r_1), \dots, (p_n, q_n, r_n) \rangle \mid \text{formula } \bigwedge_{i=1}^n (p_i \vee q_i \vee r_i) \text{ is satisfiable} \}$
 - $\mu_{3SAT}^*(\langle (p_1, q_1, r_1), \dots, (p_n, q_n, r_n) \rangle)$
 $= v_{\text{tally}}^*(1^n) \sum_{i=1}^n 2^{-(|p_i|+|q_i|+|r_i|)}$
 - (Pick up n at random and pick up n triples of variables at random.)
- A formula $\bigwedge_{i=1}^n (p_i \vee q_i \vee r_i)$ is **satisfiable** $\Leftrightarrow \exists \sigma$: truth assignment s.t. $\bigwedge_{i=1}^n (\sigma(p_i) \vee \sigma(q_i) \vee \sigma(r_i))$ equals 1

Tiles and Tilings I

- A **tile** is a quadruple $[u,v,x,w]$ of strings, where u is “left”, v is “top”, x is “right”, and w is “bottom”.
- We write **left** $[u,v,x,w]$ for u , **top** $[u,v,x,w]$ for v , **right** $[u,v,x,w]$ for x , and **bottom** $[u,v,x,w]$ for w .
- Let S_n be the $n \times n$ square $\{1, \dots, n\} \times \{1, \dots, n\}$.
- Let T be a set of tiles.
- A function $f: S_n \rightarrow T$ is a **T-tiling of S_n** if $\text{left}[f(i+1,j)] = \text{right}[f(i,j)]$ and $\text{bottom}[f(i,j+1)] = \text{top}[f(i,j)]$ for all i,j with $1 \leq i,j \leq n$.
- A sequence $\langle t_1, t_2, \dots, t_k \rangle$ is a **T-row of length k** if $t_i \in T$ for all i with $1 \leq i \leq k$ and $\text{left}[t_{j+1}] = \text{right}[t_j]$ for all j with $1 \leq j \leq k-1$.

Tiling Problem

- **Levin** (1984) discussed the distributional problem $(RBTP, \mu_{RBTP})$.
- **Randomized Bounded Tiling Problem (RBTP)**
 - **instance:** a set T of tiling, size n , a T -row $\langle t_1, t_2, \dots, t_k \rangle$ of length k with $1 \leq k \leq n$
 - **question:** is there a T -tiling f of S_n such that $f(1, i) = t_i$ for any i with $1 \leq i \leq n$?
- **Distribution μ_{RBTP} (with a fixed positive $\mu \in P$ -comp)**

$$\mu_{RBTP} \left(\langle T, 1^n, 1^k, \langle t_1, t_2, \dots, t_k \rangle \rangle \right) = \begin{cases} \mu^*(T) v_{tally}(1^n)^{\frac{1}{n}} \prod_{i=1}^k \frac{1}{|T_i|} & \text{if } \underline{\text{condition A}} \\ 0 & \text{otherwise} \end{cases}$$

where $T_i = \{ t \in T \mid \text{left}[t] = \text{right}[t_i] \}$.

- **Condition A:** $1 \leq k \leq n$ and $T_i \neq \emptyset$ for all i with $1 \leq i \leq k$

$(\text{RBTP}, \mu_{\text{RBTP}})$ is Complete for $\text{Dist}(\text{NP}, \text{P-comp})$

- **Levin** (1984) demonstrated the following completeness result.
- **(Claim)** Distributional Problem $(\text{RBTP}, \mu_{\text{RBTP}})$ is \leq_m^{P} -complete for $\text{Dist}(\text{NP}, \text{P-comp})$. [Levin (1984)]
- Note that the tiling problem is NP-complete.

Randomized Bounded Halting Problem

- We show another complete distributional problem.
- **Randomized Bounded Halting Problem (RBHP)**
 - $\text{BHP} = \{ \langle s_i, x, 1^n \rangle \mid M_i \text{ accepts } x \text{ in less than } n \text{ steps} \}$
 - $\mu_{\text{BHP}}^*(s_i, x, 1^n) = v_{\text{st}}^*(s_i) v_{\text{st}}^*(x) v_{\text{tally}}^*(1^n)$
 - (Pick up string s_i at random, pick up x at random, and pick up 1^n at random.)
- **(Claim)** $(\text{RBHP}, \mu_{\text{BHP}})$ is \leq_m^p -complete for $\text{Dist}(\text{NP}, \text{P-comp})$. [Gurevich-Shelah (1987)]

Open Problems

- There are numerous problems that have not yet solved.
 1. Find natural distributional problems that are complete for $\text{Dist}(\text{NP}, \text{P-comp})$.
 2. Similarly, find natural distributional problems that are complete for $\text{Dist}(\text{NP}, \text{P-samp})$.
- **P-samp will be discussed in the next section.**

III. Complexity of Distributions

1. P-Computable Distributions
2. Polynomial-Time Samplable Distributions
3. #P-Computable Distributions
4. E-Computable Distributions
5. Properties of Distribution Classes
6. avP-Samplable Distributions

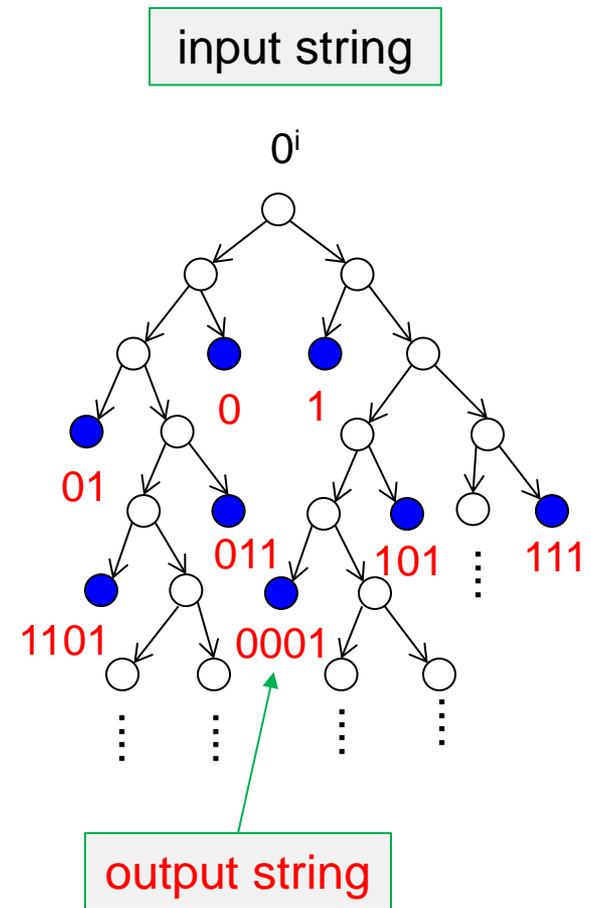

P-Computable Distributions (revisited)

- Let $\mu: \Sigma^* \rightarrow [0,1]$ be a distribution.
- Recall that μ is **polynomial-time computable** \Leftrightarrow there is a polynomial-time deterministic Turing machine (DTM) with an output tape such that $|\mu(x) - M(x,0^i)| \leq 2^{-i}$. for any $x \in \Sigma^*$ and $i \in \mathbb{N}$.
- Let **P-comp** be the collection of all polynomial-time computable distributions.

Polynomial-Time Samplable Distributions

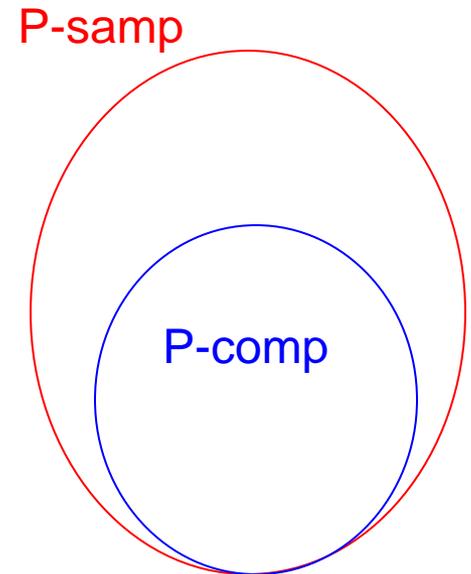

- We introduce another type of distribution.

- A distribution μ is **polynomial-time samplable** (or **P-samplable**) \Leftrightarrow there are a polynomial p and a probabilistic Turing machine (PTM) that take input 0^i and produces strings satisfying, for every x ,
 $|\mu^*(x) - \text{Prob}_M[M(0^i) \text{ produces } x \text{ within time } p(|x|,i)]| \leq 1/2^i$.

P-Samp I

- Let **P-samp** denote the collection of all polynomial-time samplable distributions.
- **(Claim)** $P\text{-comp} \subseteq P\text{-samp}$.
- **(Claim)** $P \neq NP \Rightarrow P\text{-comp} \neq P\text{-samp}$.
[Ben-David-Chor-Goldreich-Luby (1992)]
- **(Claim)** $P = PP \Leftrightarrow P\text{-comp} = P\text{-samp}$.
[Miltersen (1993)]

Many believe in this way

P-Samp II

- Recall the notion of (strong) one-way function from Week 7.
- **(Claim)** Assume that every distribution in P-samp is p-dominated by certain distributions in P-comp. Then, there is no strong one-way function [Ben-David-Chor-Goldreich-Luby (1992)]

Complete Problem for $\text{Dist}(\text{NP}, \text{P-samp})$

- We show the existence of complete distributional problem for $\text{Dist}(\text{NP}, \text{P-samp})$.
- **Randomized Bounded halting Problem (RBHP)**
 - $\text{BHP} = \{ \langle s_i, x, 1^n \rangle \mid M_i \text{ accepts } x \text{ in less than } n \text{ steps} \}$
- **Distribution μ_U**
 - Let $\{ \eta_i \}_{i \in \mathbb{N}}$ be an effective enumeration of all $O(n)$ -time samplable distributions.
 - $\mu_U^*(z) = \sum_{i=0}^{\infty} 2^{-2\lceil \log(i)+1} \eta_i^*(z)$
 - (Pick up i at random and pick up z according to η_i^* .)
- **(Claim)** (RBHP, μ_U) is \leq_m^{P} -complete for $\text{Dist}(\text{NP}, \text{P-samp})$.
[Ben-David-Chor-Goldreich-Luby (1992)]

Θ_2^P -Samplable Distributions

- A P-samplable distribution is approximated by running a certain PTM starting with input 0^i and produces strings x within time $p(|x|,i)$.

- A distribution μ is Θ_2^P -samplable if there exist a polynomial p , a constant $c > 0$, a language $A \in NP$, and an oracle PTM M such that (1) M starts with no input and A as an oracle and (2) for every x ,

$|\mu^*(x) - \text{Prob}_M[M^A(0^i) \text{ produces } x \text{ within time } p(|x|,i), \text{ making at most } c \log|x| + c \text{ queries to } A]| \leq 1/2^i.$

- Let Θ_2^P -samp to denote the class of all Θ_2^P -samplable distributions.

Invertibly P-Samplable Distributions

- Recall that $\eta_{f^{-1}}$ is defined as $\eta_{f^{-1}}^*(x) = \eta(\{z \mid f(z) = x\})$ for all strings $x \in \Sigma^*$.
- A distribution μ is **invertibly polynomial-time samplable** (or **invertible P-samplable**) if there exists a distribution $\nu \in \text{P-comp}$ and a p-honest function $f \in \text{FP}$ such that $\mu = \nu_{f^{-1}}$.
- Let **IP-samp** to denote the class of all invertibly P-samplable distributions
- Let **IP₁-samp** = $\{\nu_{f^{-1}} \mid \nu \in \text{P-comp}, f \text{ is one-one}\}$
- **(Claim)** $\text{P-comp} \subseteq \text{IP}_1\text{-samp} \subseteq \text{IP-samp}$

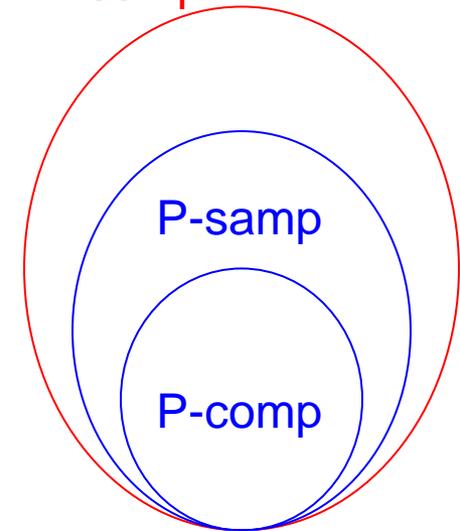

#P-Computable Distributions

- Recall that we always identify $\{0,1\}^*$ with \mathbb{N} .
- A distribution μ is **#P-computable** \Leftrightarrow there is a function $f : \{0,1\}^* \times \mathbb{N} \rightarrow \mathbb{N}$ in #P such that, for all pairs (x,i) ,

$$\left| \mu^*(x) - \frac{f(x,0^i)}{2^{p(|x|,i)}} \right| \leq 2^{-i}$$

- Let **#P-comp** be the collection of all #P-computable distributions.
- **(Claim)**
 $\text{P-comp} \subseteq \text{P-samp} \subseteq \text{\#P-comp}$

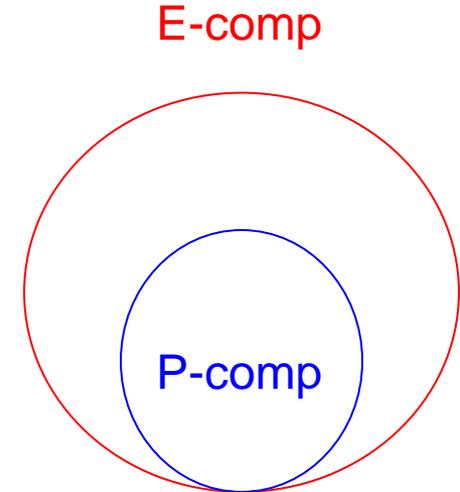

#P-comp

Many believe in this way

E-Computable Distributions

- Let $\mu: \Sigma^* \rightarrow [0,1]$ be a distribution.
- μ is **E-computable** \Leftrightarrow there is a DTM M such that, for all pairs (x,i) , M runs in time $2^{c(|x|+i)}$ and satisfies
$$| \mu(x) - M(x,0^i) | \leq 2^{-i}.$$
- Let **E-comp** be the collection of all E-computable distributions.
- **(Claim)** $P\text{-comp} \subseteq E\text{-comp}$

Many believe in this way

Properties of Distribution Classes I

- We have known the following properties of and relationships among distribution classes.
- Given a μ , $[\mu]_p$ denotes the **equivalence class** $\{ \xi \mid \xi \stackrel{p}{=} \mu \}$.
- Given two distribution sets F and G , we say that G **p-
includes** F (denoted by $F \subseteq^p G$) if $F/\stackrel{p}{=} \subseteq G/\stackrel{p}{=}$.
- **(Claim)** $\#P\text{-comp} \subseteq^p \Theta_2^p\text{-samp}$. [Schuler-Watanabe (1995)]

Properties of Distribution Classes II

- We can show the following relationships about #P-computable distributions and various P-samplable distributions.
- **Theorem:** [Yamakami (1999)]
 $P = PP \Leftrightarrow P\text{-comp} = \#P\text{-comp}$
- **Theorem:** [Yamakami (1999)]
 $P = PP \Leftrightarrow P\text{-comp} = IP_1\text{-samp} \Leftrightarrow P\text{-comp} = IP\text{-samp}$

avP-Samplable Distributions

- A distribution μ is **average polynomial-time samplable** (or **avP-samplable**) if there exists a DTM with an output tape (computing a function $f : \{0,1\}^* \times \{0\}^* \rightarrow \{0,1\}^*$) s.t.
 1. $\text{Time}_M(x, 0^i)$ is polynomial on $\nu_{\text{st}} \circ \nu_{\text{tally}}$ -average, and
 2. $|\mu^*(x) - \xi_M^{(i)}(x)| \leq 2^{-i}$

where $\xi_M^{(i)}(x) = \nu_{\text{stand}}^* \left(\left\{ y \in \{0,1\}^* \mid M(y, 0^i) = x \right\} \right)$
 $(\nu_{\text{stand}} \circ \nu_{\text{tally}})^*(x, 0^i) = \nu_{\text{stand}}^*(x) \nu_{\text{tally}}^*(0^i)$

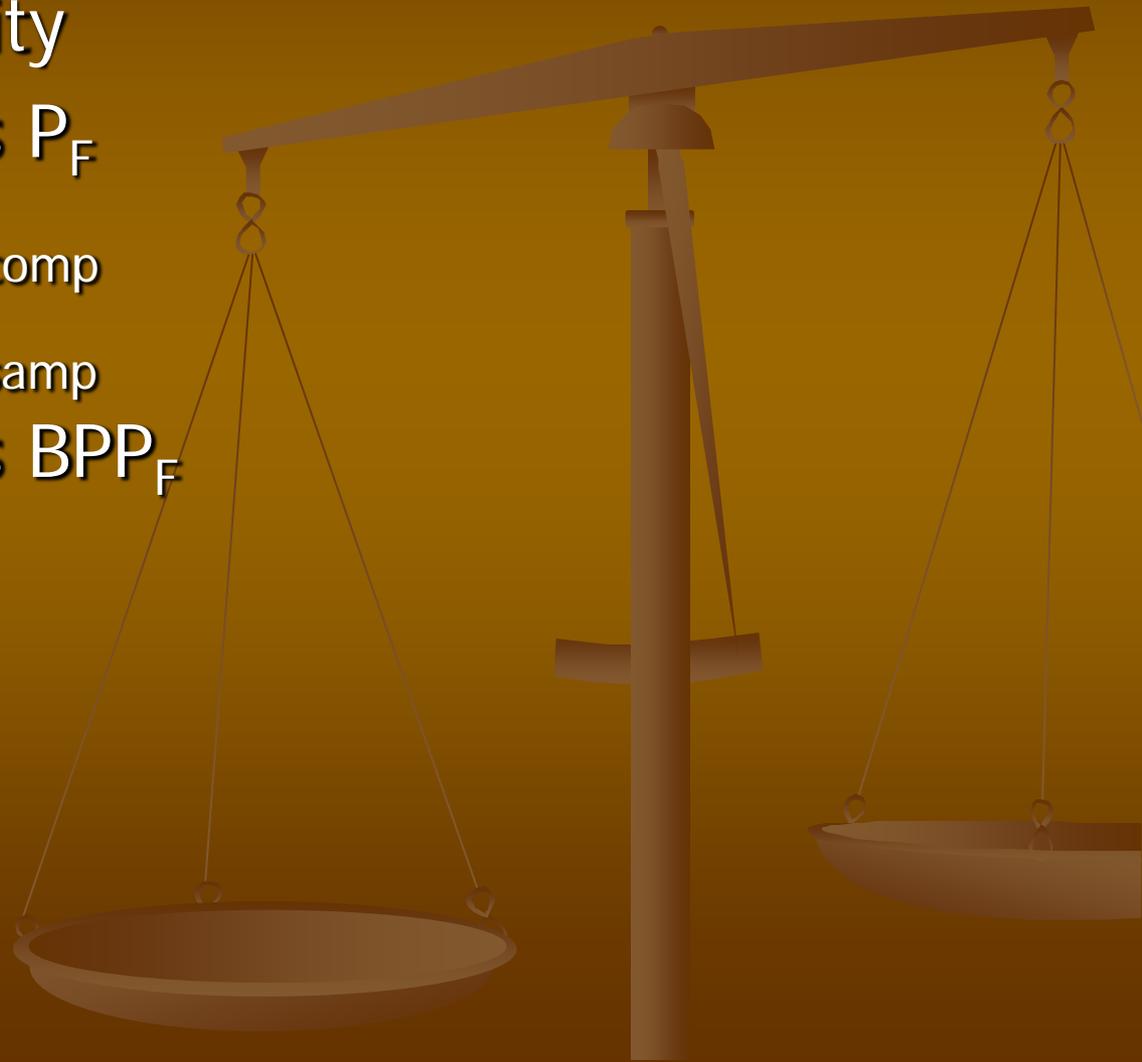

- Let **avP-samp** denote the set of all avP-samplable distributions.
- **(Claim)** $\text{P-samp} \subseteq \text{avP-samp}$

Open Problems

- There are numerous problems that have not yet solved.
 1. Does $\#P\text{-comp} =^p \text{SpanP-comp}$ imply $PP=UP$?
 2. Does $\text{avP-samp} \subseteq_{\text{av}} P\text{-comp}$ imply $P\text{-samp} \subseteq_{\text{av}} P\text{-comp}$?

IV. Real Computability

1. Real Computability
2. Complexity Class P_F
3. Properties of $P_{P\text{-comp}}$
4. Properties of $P_{P\text{-samp}}$
5. Complexity Class BPP_F

Real Computability

- We have discussed what decision problems A are solved in average polynomial-time for a reasonable distribution μ .
- In other words, $(A, \mu) \in \text{Average}(P, F)$, where F is a class of distribution.
- Let us consider decision problems that are solved in average polynomial-time for all distributions μ in F .
- Such problems are called “real” computable problems.

Complexity Class P_F

- Let F be a class of distributions.
- P_F = collection of all languages L that are polynomial-time computable on μ -average for every $\mu \in F$.
- In other words,
 $L \in P_F \iff (L, \mu) \in \text{Average}(P, F)$ holds for any $\mu \in F$.
- By taking $P\text{-comp}$, $P\text{-samp}$, $E\text{-comp}$ as F , for example, we naturally obtain $P_{P\text{-comp}}$, $P_{P\text{-samp}}$, $P_{E\text{-comp}}$, etc.
- (Claim)
 - $P \subseteq P_{P\text{-samp}} \subseteq P_{P\text{-comp}}$ (since $P\text{-comp} \subseteq P\text{-samp}$).
 - $P \subseteq P_{E\text{-comp}} \subseteq P_{P\text{-comp}}$ (since $P\text{-comp} \subseteq E\text{-comp}$).

Properties of $P_{P\text{-comp}}$

- Here is a short list of properties known today.
 1. $P = P_{E\text{-comp}}$ [Schuler-Yamakami (1995)]
 2. $P \neq P_{P\text{-comp}}$ [Schuler (1995)]
 3. $P_{P\text{-comp}} \not\subseteq P/cn$ for any fixed $c > 0$ [Schuler-Yamakami (1995)]
 4. $NP \subseteq P_{P\text{-comp}}$ implies $P = BPP$. [Buhrman-Fortnow-Pavan (2005)]
 5. $NP \subseteq P_{P\text{-comp}}$ implies $E = NE$ [Ben-David-Chor-Goldreich-Luby (1992)]
 6. $NP \subseteq P_{P\text{-comp}}$ implies $MA = NP$ [Köbler-Schuler (2004)]
 7. $\Delta_3^P \subseteq P_{P\text{-comp}}$ implies $\Sigma_3^P \cap \Pi_3^P \cap P/poly = P$ [Köbler-Schuler (2004)]

Properties of $P_{P\text{-samp}}$

- Here is a short list of properties known today.
 1. $P \subseteq P_{P\text{-samp}} \subseteq E$ and $P \neq P_{P\text{-samp}} \neq E$ [Schuler (1995)]
 2. $NP \subseteq P_{P\text{-comp}}$ implies $NP \subseteq P_{P\text{-samp}}$. [Buhrman-Fortnow-Pavan (2005)]
 3. $NP \subseteq P_{P\text{-samp}}$ implies $\Theta_2^P \subseteq P_{P\text{-samp}}$ [Ben-David-Chor-Goldreich-Luby (1992), Schuler-Watnabe (1995)]

Complexity Class BPP_F

- Let F be any set of distributions.
- BPP_F is composed of all languages L such that, for every $\mu \in F$, there is a probabilistic Turing machine (PTM) M that recognizes L with probability at least $2/3$ in time polynomial on μ -average.
- **(Claim)** $BPP \subseteq BPP_F \subseteq BPE$ if $v_{st} \in F$. [Yamakami (1999)]
- **(Claim)** $MA \subseteq BPP_{P\text{-comp}} \rightarrow MA_E \subseteq BPE$. [Yamakami (1999)]
- **(Claim)** $NP \subseteq BPP_{P\text{-comp}} \rightarrow NE \subseteq BPE$. [Schuler-Yamakami (1992)]

Open Problems I

- Here is a short list of open problems associated with real computability.
 1. Is $P_{P\text{-comp}} \subseteq P/\text{poly}$?
 2. Is $P_{P\text{-comp}} \subseteq \oplus P$?
 3. Does $BPP \subseteq P_{P\text{-comp}}$ imply $P = BPP$?
 4. Does $NP \subseteq P_{P\text{-comp}}$ imply $P = NP$?
 5. Is $MA \subseteq BPP_{P\text{-comp}}$?
 6. Is $BPP \neq BPP_{P\text{-comp}}$?
 7. Does $NP \subseteq P_{P\text{-comp}}$ imply $P\text{-samp} \leq^p P\text{-comp}$?

Open Problems II

- Here is a short list of open problems associated with real computability.
 1. Is $MA \subseteq BPP_{P\text{-comp}}$?
 2. Is $P_{P\text{-comp}} \subseteq \oplus P$?
 3. Is $MA \subseteq P_{P\text{-comp}}$ equivalent to $MA \subseteq P_{P\text{-samp}}$?
 4. avP-samp Does $BPP \subseteq P_{P\text{-comp}}$ imply $P = BPP$?
 5. Does $NP \subseteq P_{P\text{-comp}}$ imply $P = NP$?
 6. Is $MA \subseteq BPP_{P\text{-comp}}$?
 7. Is $BPP \neq BPP_{P\text{-comp}}$?
 8. Does $NP \subseteq P_{P\text{-comp}}$ imply $P\text{-samp} \leq^p P\text{-comp}$?

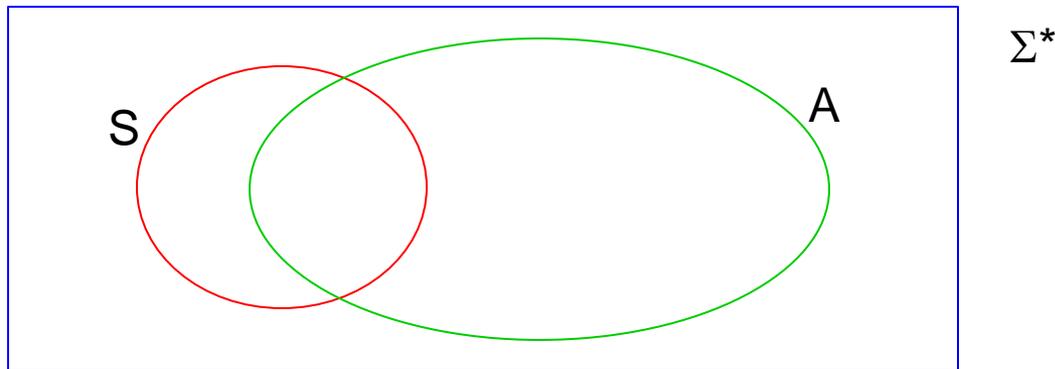

V. Nearly BPP

1. Nearly BPP Sets
2. Properties of Nearly-BPP

Nearly-BPP Sets

- A language A is said to be **nearly-BPP** if, for every polynomial p , there exist a set S and a polynomial-time probabilistic Turing machine M such that, for each x ,
 1. $x \in \Sigma^* - S \rightarrow \text{Prob}_M[M(x) \neq A(x)] \leq 1/3$, and
 2. $\text{Prob}_{x \in \Sigma_n}[x \in S] < 1/p(n)$ for almost all n .

- Let **Nearly-BPP** be the class of all nearly-BPP languages.

Properties of Nearly-BPP

- We show several properties of **Nearly-BPP**.
- The notation \neq^{avp} is the negation of \approx^{avp} discussed earlier.
- **Theorem:** [Yamakami (1999)]
 1. $\text{BPP}_{\text{P-comp}} \subseteq \text{Nearly-BPP}$.
 2. $\text{NP} \not\subseteq \text{Nearly-BPP}$, then $\text{P-comp} \neq^{\text{avp}} \text{IP}_1\text{-samp}$.
 3. If strong one-way function exists, then $\text{NP} \not\subseteq \text{Nearly-BPP}$.

Open Problems

- There are numerous open problems.
 1. Does $\text{NP} \subseteq \text{Nearly-BPP}$?
 2. Does $\Delta_2^{\text{P}} \subseteq \text{Nearly-BPP}$?
 3. Does $\oplus\text{P} \subseteq \text{Nearly-BPP}$?
 4. Develop a nice theory of complexity classes Nearly-C for reasonable class C ?
